PREFACE

This book describes the physical polymer molecules are synthesize reader to the characteristic that chomologs (Chap. 1) and then proof polymerization reactions—step 2–5, 7). Polymerization reactions thermodynamic features, their soo polymer structures, and the proceed the property of t

and that is available to the synthet. The versatility of polymerizatio that can be polymerizate but also stereospecific polymerization. According to the control of the control of the control of polymerization and is considere are discussed in the appropriate che polymerization with emphasis on tures by the appropriate choice of polymerist polymerization of polymers that as structures and the use of polymeri. The literature has been covered it

This book is intended for chem experienced polymer chemist. The polymers for the former. Each topi ot alter the \$\frac{1}{2}\$-power dependence of echanism indicates a more complex asses monotonically from 1.2 to 0.4 particles is higher and the nucleation oncentrations. Polymer particle forere is a greater tendency for capture 1 the latter concentrations are high. 11, there is compatibility with the \$\frac{1}{2}\$-\$\frac{

tendency toward radical desorption. on S and Ri, respectively. This result, nucleation since one cannot preclude larger and smaller, respectively, than t than those studied. Monomers such v Case 1 behavior, tend to show a by Eq. 4-11, indicating the presence ependence of N on Ri deviates marksorption occurs, the large fraction of the result that N is little affected by is 0.64 for styrene, 0.86 for methyl or vinyl acetate, while the orders of ctively [Hansen and Ugelstad, 1979a, /lonitrile and butyl acrylate shows a and S from 0.67 to 0.40 with increasing ctant was used [Capek et al., 1988]. ion in the presence of a cationic sur-

ne emulsion polymerizations—inverse oncentration. Some surfactants act as illy of the more highly reactive radicals and Motoyama, 1962; Stryker et al., possessing unsaturation (e.g., certain ough allyl hydrogens is probably quite

iring Intervals II and III since the total coverage of the surface with surfactant lity appears to be insufficient to cause since N is generally observed to be lity decreases sufficiently to cause the version [Blackley, 1975].

ILSION POLYMERIZATION

n are water-soluble initiators such as peroxide, and 2,2'-azobis(2-amidinoble peroxides such as succinic acid perounds such as 4,4'-azobis(4-cyanopenms such as persulfate with ferrous ion (Eq. 3-38a) are commonly used. Redox systems are advantageous in yielding desirable initiation rates at temperatures below 50°C. Other useful redox systems include cumyl hydroperoxide or hydrogen peroxide with ferrous, sulfite, or bisulfite ion.

4-3b Surfactants

Anionic surfactants are the most commonly used surfactants in emulsion polymerization [Blackley, 1975; Gardon, 1977]. These include fatty acid soaps (sodium or potassium stearate, laurate, palmitate), sulfates, and sulfonates (sodium lauryl sulfate and sodium dodecylbenzene sulfonate). The sulfates and sulfonates are useful for polymerization in acidic medium where fatty acid soaps are unstable or where the final product must be stable toward either acid or heavy-metal ions. Nonionic surfactants such as poly(ethylene oxide), poly(vinyl alcohol) and hydroxyethyl cellulose are sometimes used in conjunction with anionic surfactants for improving the freeze-thaw and shear stability of the polymer or to aid in controlling particle size and size distribution. The presence of the nonionic surfactant imparts a second mode of colloidal stabilization, in addition to electrostatic stabilization by the anionic surfactant, via steric interference with the van der Waals attraction between polymer particles. Nonionic surfactants are also of use where the final polymer latex should be insensitive to changes in pH over a wide range. Nonionic surfactants are only infrequently used alone, since their efficiency in producing stable emulsions is less than that of the anionic surfactants. Anionic surfactants are generally used at a level of 0.2-3 wt % based on the amount of water; nonionic surfactants are used at the 2-10% level. Cationic surfactants such as dodecylammonium chloride and cetyltrimethylammonium bromide are much less frequently used than anionic surfactants because of their inefficient emulsifying action or adverse effects on initiator decomposition. Also, cationic surfactants are more expensive than anionic surfactants.

Surfactants increase particle number and decrease particle size as their concentration in the initial reaction charge is increased. However, one can use delayed addition of surfactant after nucleation is complete to improve particle stability, without affecting the particle number, size, and size distribution.

4-3c Other Components

The quality of the water used in emulsion polymerization is important. Deionized water may be used since the presence of foreign ions or ions in uncontrolled concentrations can interfere with both the initiation process and the action of the emulsifier. Antifreeze additives are used to allow polymerization at temperatures below 0°C. These include inorganic electrolytes as well as organics such as ethylene glycol, glycerol, methanol, and monoalkyl ethers of ethylene glycol. The addition of inorganic electrolytes often affects the polymerization rate and stability of the emulsion. Sequestering agents such as ethylenediamine tetrascetic acid or its alkali metal salts may be added to help solubilize a component of the initiator system or to deactivate traces of calcium and magnesium ions present in the water. Buffers such as phosphate or citrate salts may be used to stabilize the latex toward pH changes.

4-3d Propagation and Termination Rate Constants

Emulsion polymerization proceeds in a polymer particle where the concentration of polymer is quite high throughout the reaction. This type of system is then similar to
